## Assignment - 3

---

**Course Title: Advanced Econometrics-II**  
**Course Code: 408**

**Prepared by:**

**Shapnil Das**  
**Roll: JN-135-081**  
**Section: B**  
**Registration: 2021-914-759**

**Prepared for:**

**Sayed Jubair Bin Hossain**  
**(Lecturer)**  
**Department of Economics,**  
**University of Dhaka**

### Question:

---

Attached is a STATA data file with a time series variable "y". First, using the Box-Jenkins methodology, determine which ARMA model this variable follows. After estimating the ARMA model, please forecast 10 steps ahead of "y" with a 95% confidence interval. Extra marks for better visual representation.

### Solution:

---

Following the Box-Jenkins Methodology, we will follow (a) Identification (b) Estimation (c) Diagnostic Test, these 3 procedures to find the best Univariate ARMA model that this variable y follows.

#### *(a) Identification:*

H0: Random walk without drift,  $d = 0$

|      | Test       | Dickey Fuller<br>Critical Values |        |        |
|------|------------|----------------------------------|--------|--------|
|      | Statistics | 1%                               | 5%     | 10%    |
| Z(t) | -3.622     | -3.517                           | -2.894 | -2.582 |

MacKinnon approximate p-value for Z(t) = 0.0054

The Time Series plot of the variable y clearly shows no significant trend. And the Augmented Dickey-Fuller Test also rejects the Null Hypothesis of a Unit Root Process at lag 4. So, we can conclude that variable y is stationary.

Both the Autocorrelation and Partial Auto-correlation Function of y variable show significant spikes till lag 3 and exponential decay. So, I assume the presence of ARMA (2,3), ARMA (3,2), ARMA (3,3), ARMA (3,4), ARMA (4,3). Now I will estimate all the assumed models and compare their information criteria to get the parsimonious model.

Information Criteria:

| <i>Model</i> | <i>N</i> | <i>LL (model)</i> | <i>df</i> | <i>AIC</i> | <i>BIC</i> |
|--------------|----------|-------------------|-----------|------------|------------|
| ARMA (2,3)   | 100      | -124.3935         | 7         | 262.7871   | 281.0233   |
| ARMA (3,2)   | 100      | -125.8966         | 7         | 265.7933   | 284.0295   |
| ARMA (3,3)   | 100      | -124.1635         | 8         | 264.327    | 285.1684   |
| ARMA (3,4)   | 100      | -123.6252         | 9         | 265.2504   | 288.6969   |
| ARMA (4,3)   | 100      | -123.5017         | 9         | 265.0035   | 288.45     |

Among those guessed model, ARMA (2,3) yields the lowest AIC and BIC so this is my chosen Univariate model for the variable y.

*(b) Estimation:*

| <b>ARIMA (2,3) regression</b> |       |         |                    |         |           |           |     |
|-------------------------------|-------|---------|--------------------|---------|-----------|-----------|-----|
| y                             | Coef. | St.Err. | t-value            | p-value | [95% Conf | Interval] | Sig |
| Constant                      | .219  | .51     | 0.43               | .668    | -.781     | 1.218     |     |
| ar                            |       |         |                    |         |           |           |     |
| L                             | 1.601 | .146    | 10.94              | 0       | 1.314     | 1.888     | *** |
| L2                            | -.731 | .12     | -6.12              | 0       | -.966     | -.497     | *** |
| ma                            |       |         |                    |         |           |           |     |
| L                             | -.352 | .145    | -2.43              | .015    | -.636     | -.068     | **  |
| L2                            | -.374 | .127    | -2.95              | .003    | -.623     | -.126     | *** |
| L3                            | .476  | .116    | 4.11               | 0       | .249      | .702      | *** |
| Constant                      | .828  | .057    | 14.52              | 0       | .716      | .94       | *** |
| Mean dependent var            |       | 0.275   | SD dependent var   |         |           | 2.162     |     |
| Number of obs                 |       | 100     | Chi-square         |         |           | 867.399   |     |
| Prob > chi2                   |       | .       | Akaike crit. (AIC) |         |           | 262.787   |     |

\*\*\*  $p < .01$ , \*\*  $p < .05$ , \*  $p < .1$

After estimating the ARMA (2,3) model we can see all the lag coefficients of AR and MA process are statistically significant at 1% confidence intervals. And the roots diagram shows us that all the roots of AR and MA process are within the unit circle. So, we can say ARMA (2,3) model is acceptable for estimation.

(c) Diagnostic Test:

Portmanteau test for white noise

---

Portmanteau (Q) statistics = 33.0943

Prob > chi2(40) = 0.7721

The Ljung-Box test or Q test at lag 40 do not reject the Null Hypothesis of the residuals being white noise. The Autocorrelation and Partial Autocorrelation function of the residuals also justify this white noise process for lag 20. This diagnostic test satisfies the residuals being

white noise and according to the steps of Box Jenkins Methodology ARMA (2,3) model is accepted as the univariate process of the variable  $y$ .

*(d) 10 Steps Ahead Forecast:*
